What are the health risks for survivors who use tobacco?

Cigarette smoking not only causes cancer but also can negatively impact cancer treatment and survival. In the US, 9% to 18% of survivors smoke cigarettes. A higher percentage of survivors younger than 40 years smoke cigarettes compared with older survivors. Psychosocial factors, including distress, are associated with cigarette smoking among survivors.

- Having poorer response or outcomes to treatment (treatment toxicity).
- Having their cancer recur.
- Developing a new primary cancer.
- Dying from their primary cancer or from a secondary cancer.
- Dying from other causes such as pneumonia and infection.

Quitting tobacco can improve a survivor’s prognosis. Patients who receive advice about cessation from their provider are more likely to quit tobacco use.

Health care providers can help survivors quit tobacco use.

- Talk with survivors about the risks of tobacco use after a cancer diagnosis.
- Ask survivors whether they use tobacco products, encourage those who do to quit, and assess their willingness to quit.
- Help survivors quit by prescribing FDA-approved cessation medications and referring them to tobacco cessation counseling services, when indicated.
- Ensure that tobacco cessation medications and counseling services are outlined as part of a survivorship care plan, when indicated.
- Follow-up with survivors regularly about their tobacco use.
- Identify and address psychosocial issues as part of recommended distress screening, when indicated.

---

Tobacco use can cause many cancers throughout the body.

**10% to 80%** of deaths from these tobacco-related cancers are caused by cigarette smoking:

- **47%** Oral Cavity and Pharynx
- **77%** Larynx
- **51%** Esophagus
- **80%** Lung, Bronchus, and Trachea
- **20%** Stomach
- **17%** Kidney and Renal Pelvis
- **12%** Pancreas
- **24%** Liver
- **45%** Urinary Bladder
- **22%** Uterine Cervix
- **10%** Colon and Rectum
- **15%** Acute Myeloid Leukemia
